#### 1.0 Problem Identification Overview

The United States Consumer Price Index ("Inflation") is calculated by the U.S. Bureau of Labor Statistics. It has gone through various periods of prominent increases; notably in the 1920's, 1940's, & 1970's. Otherwise, it has remained relatively constant or declining.

Inflation is important in all facets of life but the financial world pays special attention to it as the key objectives of the Federal Reserve are maximizing employment, stabilizing prices & moderating long-term interest rates; the second of which is Inflation & the third of which is generally decided by the condition of the other two (2). Their decisions can move financial markets around the world; we won't go into that here. In short, Inflation is an important component of developing investment strategies for portfolios across the world. The view on inflation becoming positive or negative in the future is not agreed upon nor are the variables which influence it.

The purpose of this Data Science project is to develop a model to help understand the phenomenon of Inflation. Nineteen (19) variables ("Variables") were shortlisted to determine their influence on Inflation; Appendix I.

#### 2.0 Generated Deliverables

The following Application Programming Interface's ("API") were used to pull the relevant data:

- 1. Quandl
- 2. Investing.com ("Investpy")
- 3. Federal Reserve Economic Data ("FRED")

The data retrieved by the API's are from sources highlighted in Appendix I.

Using these, three (3) deliverables were generated:

- 1. The source code for the modeling developed to analyze the aforementioned problem ( link )
- 2. This document outlining the process
- 3. A PDF presentation with our findings (link)

#### 3.0 Data Pre-Processing Steps

#### Data Cleaning:

- 1. The data for the Variables & Inflation were first pulled using the API's
- 2. The result produced a data frame with non-congruent lengths in time ( Appendix II )
- 3. It was required to draw the line at the 18 April 1990 to ensure they aligned appropriately (Appendix II)
- 4. This resulted in a Daily (Mon-Fri (excluding holidays)) comprised of 9,752 non-null float values (Appendix II)
- 5. The Variables were concatenated with Inflation which resulted in a data frame with 321 observations ( Appendix II )
- 6. This data frame was used to cross reference the accuracy of the next steps in Exploratory Data Analysis

#### **Exploratory Data Analysis:**

Which time periods for percent changes to use for the Variables & Inflation wasn't confirmed. The first step was to run through the process on multiple configurations with Winsorization on Inflation as per below:

- 1. Quarter-on-Quarter
  - a. **Description** | Looking at Quarterly percent changes in both Variables & Inflation
  - b. Inflation Winsorization | +3% & -2%
  - c. Average Pearson Coefficient | 22.64%
- 2. Month-on-Month
  - a. Description | Looking at Monthly percent changes in both Variables & Inflation
  - b. Inflation Winsorization | ±1%
  - c. Average Pearson Coefficient | 18.22%
- 3. Quarter-on-Quarter for Variables ( past ) & Inflation ( forwards )
  - a. Description | Looking at Quarterly percent changes on Variables looking backwards while forward looking Quarterly changes on Inflation to ascertain if changes in the Variables took time to reach Inflation
  - b. Inflation Winsorization | +2.51% & -2.84%
  - c. Average Pearson Coefficient | 12.18%
- 4. Quarter-on-Quarter w/ Rolling Averages on Daily, Weekly & Monthly Variables
  - a. **Description** | This approach is similar to # 1 albeit used a rolling average for those that reported more often than once a Quarter. The rational was that a Variable may have had a bad week or day when the Quarter ended; as such, the entire changes throughout the Quarter may need to be accounted for evenly
  - b. Inflation Winsorization | ±3%
  - c. Average Pearson Coefficient | 30.21%

It was also observed that Winsorization on Inflation in #4 above (Best) reduced the average Pearson Coefficient score. The results before Winsorization are below:

#### 5. Quarter-on-Quarter w/ Rolling Averages ( without Inflation Winsorized )

- a. **Description** | Same as #4 above less Winsorization on Inflation
- b. Inflation Winsorization | n/a
- c. Average Pearson Coefficient | 30.95%

It was decided that Winsorization did not work on the Inflation data herein; thus, Inflation was not Winsorized & this data frame was chosen to move on.

While Winsorization may not work on Inflation, that does not mean it doesn't work on the Variables. Eight (8) variables were chosen to be Winsorized. These saw an average increase in their Pearson correlation coefficients of 173 bps with one seeing a 460 bps increase. Our final round presented the following:

- 6. Quarter-on-Quarter w/ Rolling Averages ( without Inflation Winsorized & 8 Variables Winsorized )
  - a. Description | Same as #5 above but 8 variables Winsorized
  - b. Inflation Winsorization | n/a
  - c. Average Pearson Coefficient | 31.67%

The "Win\_plus" column in the chart on the right, shows each of the variables improvement with Winsorization. If it's a Zero, the Variable wasn't chosen.

Wage CPI	0.595358	0.595358	0.000000	n/a
WTI	0.540347	0.541041	0.000694	Winsorized

PMI	0.223222	0.223222	0.000000	n/a
USD Index	0.307158	0.307158	0.000000	n/a
Unemployment Rate	0.215974	0.261978	0.046005	Winsorized
Initial Jobless Claims	0.272464	0.297205	0.024741	Winsorized

NoWinzor p

Win p Win plus Winsorized?

The Feature Correlation Heat Maps with the Pearson correlation coefficients of each variable against Inflation are found in Appendix III; these go into greater detail on the Average Pearson Coefficient (c) above. Scatter Plots for those Winsorized are in Appendix IV; all others are in the source code.

In summary, the Best Configuration (#6) was chosen as it presented the most optimal Pearson correlation coefficients to achieve our goal of developing a model to understand the phenomenon of Inflation.

#### Pre-processing:

- 1. The first step in pre-processing, per the Machine Learning process, was to create a "Best Guess" number. The standard mean & DummyRegressor functions were used. The data frame has no categorical data so **this step** was purely to "go through the process" but **is irrelevant**; **please disregard when reading the source code**
- 2. The next step was to split the data into training & testing data frames, 70% & 30% respectively
- 3. Next was to scale the data. There is no certainty to which scaling technique to use & thus, the following were all applied on both the X & y variables & X only (x6 in total):
  - a. Standard Scaling (SS)
  - b. MinMax Scaling ( MM )
  - c. Log Transformation (LG)
- 4. The Variables were divided into selected groups to apply SS, MM & LG separately to where SS, MM & LG may be better suited; they were concatenated with Inflation
- 5. The **initial results** ( Appendix V ) showed that MM presented negative results for R<sup>2</sup> on the test set. The Mean Absolute Error ( MAE ) & the Root Mean Squared Error ( RMSE ) presented a mixed bag for the MM structure. It was decided that due to this relative uncertainty & negative R<sup>2</sup>, the MM structure was taken out of consideration.
- 6. Five (5) scaling approaches were used & it was determined that all showed results that should be put to the process of the Random Forest Generator to identify the best Variables presented below & in <a href="Appendix VI">Appendix VI</a>.

```
R<sup>2</sup> results for X & y scaled below
SS Train | 0.5055 Test 0.2962
LG Train | 0.4983 Test 0.2781

R<sup>2</sup> results for X only scaled below
SS Train | 0.5133 Test 0.2925
LG Train | 0.5005 Test 0.2732

R<sup>2</sup> results for the LG & SS combination below
SS Train | 0.5053 Test 0.2788
```

#### 4.0 Model Description

Although Dummy Regressor & Linear Regression analysis was undertaken, they were discounted due to the data frame being entirely float based & displayed comparatively worse performance respectively. Therefore, the Random Forest Model was used with the goal of determining what variables best explain Inflation.

#### 5.0 Model Findings

As the purpose of this Data Science project is to develop a model to explain & understand the phenomenon of Inflation, the following process was undertaken on the five (5) shortlisted scaling approaches:

- 1. Grid Search
- 2. Random Forest
- 3. Hyperparameter search using Grid Search CV

The final outcomes can be seen in Appendix VII.

WTI held a ubiquitous position as being the dominate Variable on all scaling approaches. This may be justified due to its connection with many activities in the United States. Heating Oil, a byproduct using WTI, & Wages CPI stayed in second & third place on many respectively.

Nevertheless, they weren't the only ones helping improve the k-value. The total number of variables ranged from 9 to 11 & the breakdown is in <a href="Appendix VII">Appendix VII</a> for review.

The variables that were not helping were then removed for each & the process was run the last time. The results are below:

```
MAE results for X & y scaled below
R<sup>2</sup> results for X & y scaled below
                                                                                                            RMSE results for X & y scaled below
SS Train | 0.492 Test 0.2706
LG Train | 0.4682 Test 0.2862
                                                   SS Train | 0.5143 Test 0.6133
LG Train | 0.5261 Test 0.5955
                                                                                                           SS Train | 0.7128 Test 0.8232
LG Train | 0.7292 Test 0.8171
R<sup>2</sup> results for X only scaled below
                                                    MAE results for X only scaled below
                                                                                                            RMSE results for X only scaled below
SS Train | 0.492 Test 0.2734
LG Train | 0.7563 Test 0.6524
                                                    SS Train | 0.4526 Test 0.6034
LG Train | 0.2229 Test 0.294
                                                                                                            SS Train | 0.6272 Test 0.8216
LG Train | 0.4343 Test 0.5702
R2 results for the LG & SS combination below MAE results for the LG & SS combination below RMSE results for the LG & SS combination below
SS Train | 0.4776 Test 0.2918
                                                   SS Train | 0.2229 Test 0.294
                                                                                                             SS Train | 0.4343 Test 0.5702
```

After review of the Test set results (the arbiter), the LG on X only was chosen amongst the other scaling approaches given it had the highest R<sup>2</sup> & tied as the lowest MAE & RMSE.

So how do these test results compare to those presented in the Pre-processing step?

```
Comparing final to the averages in the Pre-processing Step 37.92 bps increase in R<sup>2</sup>

A -23.52 bps decrease in MAE

A -15.28 bps decrease in RMSE
```

Our conclusion on how to explain & understand the phenomenon of Inflation is a reconfiguration of words used by James Carville (link) | It's Oil, silly.

#### 6.0 Next Steps

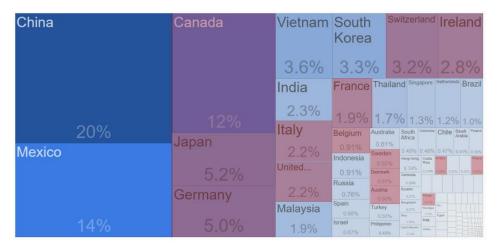

Inflation is a difficult & highly disputed financial beast but the closer you get to taming it, your eyes will open wider.

Throughout the process there were a number of actions & variables that may have been done or included. **Highlighted** below are some Variables which were not included due to financial & time constraints:

- 1. Steel
  - Could only identify data back to 2008
- 2. Gasoline
  - Could only identify data back to 2005
- Growth of M2
  - Put it aside to mitigate any collinearity with M2 Velocity
- 4. US Wages Hourly Earnings
  - Limited data as well
- 5. US Dollar Index: Broad, Goods and Services
  - This only goes back to 2006

Further to these, further consideration may be applicable to the below:

- 1. The big set back would be the size of the data frame. With only 321 observations, machine learning is limited
- 2. Winsorization on Inflation & other variables may be re-examined
- 3. Reassess the Variables chosen in the SS & LG divide; discussed in Pre-processing above
- 4. Develop a model to predict Wages CPI itself in order to minimize reliance on US gov't reporting
- 5. It is believed that the US Dollar Index Variable ( DXY ) does not correctly address the relationship of US Imports on Inflation. This may be because the DXY's weighting does not correctly align to US trade. In short, it's a weighted geometric mean of the currencies in the Eurozone ( EUR ), Japan ( JPY ), the United Kingdom ( GBP ), Canada ( CAD ), Sweden ( SEK ) & Switzerland ( CHF ) but that does not correctly align with US trade with the world
  - o Highlighted below is the US Import Trade in 2020 by country; in red are those in the DXY
  - It only accounts for under ~40%

There are a number of Variables to take into consideration. For now, the machine recommends keeping an eye on Oil.

Items	Reported	API	API Source	Comments
Inflation	Monthly	Quandl	U.S. Bureau of Labor Statistics	The target variable
